ABSTRACT

In this article, xxx

Index Terms— Generative Models; Variational Inference; Semi-Supervised Learning; Triplet Markov Chains.

1. INTRODUCTION

Let $\mathbf{x}_T = (x_0, \dots, x_T)$ and $\mathbf{z}_T = (z_0, \dots, z_T)$ be two sequences of observed and latent random variables (r.v.), respectively, where $x_t \in \mathbb{R}^{d_x}$ and $z_t \in \mathbb{R}^{d_z}$. We also define a third process of discrete values $\mathbf{y}_T = (y_0, \dots, y_T)$, where $y_t \in \Omega = \{\omega_1, \dots, \omega_C\}$. As far as notations are concerned, we do not distinguish r.v. and their realizations.

1.1. Semi-Supervised learning

Sequential data is characterized by a temporal ordering of observations. It is commonly used in many fields, such as speech recognition XX, natural language processing XX, and activity recognition XX, etc. Labeled sequential data is sequential data that is annotated with labels that indicate the meaning or class of each observation. These labels are essential for many applications, such as supervised classification, anomaly detection, and clustering. However, in many real-world applications, it is expensive or impossible to obtain labels for the entire sequence due to various reasons such as the high cost of labeling, the lack of expertise, or the lack of time. In such cases, partially labeled sequential data, which only has labels for some of the observations, can be used instead.

Partially labeled sequential data presents a challenging problem for machine learning algorithms XX because they need to leverage both the labeled and unlabeled parts of the data to learn a good model. This problem is known as semi-supervised learning, and it has been studied extensively in the machine learning community, it can be handle using different techniques XXX. In particular, generative models are a popular approach for semi-supervised learning, as they allow the incorporation of prior knowledge about the data distribution. In the case of sequential data, probabilistic generative models can be used to model the underlying distribution of the data

and generate new samples, make predictions outcomes, and estimate missing or unobserved data.

One approach for semi-supervised learning is to design a latent variable generative model, which can represent complex temporal relations, and then propose a variational method for learning and inference XXX. Some popular examples of generative models include Hidden Markov Chains (HMCs) [1] and Pairwise Markov Chains (PMCs) [2, 3] which are used for modeling sequential data and are based on latent variables. However, they have not been adapted to the case of partially labeled sequential data...

In this article, we propose a more general generative model called Triplet Markov Chain (TMC) [4, 5]

1.2. Scope of the paper

Since only a subset of the observations has corresponding labels, the sequence of labels can be expressed as $\mathbf{y}_T = \mathbf{y}_{T^{\mathcal{L}}} \cup \mathbf{y}_{T^{\mathcal{U}}}$, where $\mathbf{y}_{T^{\mathcal{L}}} = \{y_t\}_{t \in \mathcal{L}}$ and $\mathbf{y}_{T^{\mathcal{U}}} = \{y_t\}_{t \in \mathcal{U}}$ are the sets of observed labels and unobserved (hidden) labels, respectively; and \mathcal{L} and \mathcal{U} are the set of labeled and unlabeled time steps, respectively.

In this article, our interest is to present a general generative model for semi-supervised learning, based on latent r.v. which is defined by a joint distribution $p_{\theta}(\mathbf{x}_T, \mathbf{y}_T, \mathbf{z}_T)$ and provides learning from the observations \mathbf{x}_T and the observed labels $\mathbf{y}_{T^{\mathcal{L}}}$, since the distribution reads

$$p_{\theta}(\mathbf{x}_T, \mathbf{y}_{T^{\mathcal{L}}}) = \sum_{\mathbf{y}_{T^{\mathcal{U}}}} \int p_{\theta}(\mathbf{x}_T, \mathbf{y}_T, \mathbf{z}_T) d\mathbf{z}_T. \quad (1)$$

Our model is based on the TMC [4, 5] which relies on the assumption that the triplet $(z_t, y_t, x_t)_{t \geq 0}$ is a Markov chain with transition $p(z_t, y_t, x_t | z_{t-1}, y_{t-1}, x_{t-1})$.

2. PROPOSED METHOD

This section presents a review of variational Bayesian inference and its application to general Triplet Markov Chains for semi-supervised learning.

Anonymous.

2.1. Background: Variational Inference

The aim is to estimate the parameter θ from a realization \mathbf{x}_T . A popular estimate is the Maximum-Likelihood (ML) estimate $\hat{\theta} = \arg \max_{\theta} p_{\theta}(\mathbf{x}_T)$ due to its statistical properties [6, 7]. However, a direct maximization of $p_{\theta}(\mathbf{x}_T)$ is not always possible, particularly in models with latent variables where the likelihood $p_{\theta}(\mathbf{x}_T) = \int p_{\theta}(\mathbf{x}_T, \mathbf{z}_T) d\mathbf{z}_T$ may be not computable. In the variational inference framework, a variational lower bound called evidence lower bound (ELBO) on the log-likelihood is optimized in order to estimate the parameters θ . This variational lower bound relies on the introduction of a parameterized variational distribution $q_{\phi}(\mathbf{z}_T|\mathbf{x}_T)$, which is parameterized by a set of parameters ϕ , and it is given by:

$$\log(p_{\theta}(\mathbf{x}_T)) \geq \tilde{Q}(\theta, \phi),$$

$$\tilde{Q}(\theta, \phi) = - \int \log \left(\frac{q_{\phi}(\mathbf{z}_T|\mathbf{x}_T)}{p_{\theta}(\mathbf{x}_T, \mathbf{z}_T)} \right) q_{\phi}(\mathbf{z}_T|\mathbf{x}_T) d\mathbf{z}_T. \quad (2)$$

Equality holds if $q_{\phi}(\mathbf{z}_T|\mathbf{x}_T) = p_{\theta}(\mathbf{z}_T|\mathbf{x}_T)$. When the posterior distribution $p_{\theta}(\mathbf{z}_T|\mathbf{x}_T)$ is computable, the alternating maximization w.r.t. θ and q_{ϕ} of the ELBO, $\tilde{Q}(\theta, \phi)$, coincides with the EM algorithm [8].

Variational inference consists in maximizing $Q(\theta, \phi)$ with respect to (θ, ϕ) for a given class of distributions q_{ϕ} . The choice of the variational distribution $q_{\phi}(\mathbf{z}_T|\mathbf{x}_T)$ is important; $q_{\phi}(\mathbf{z}_T|\mathbf{x}_T)$ should be close to $p_{\theta}(\mathbf{z}_T|\mathbf{x}_T)$ but should also be chosen in a such way that the associated ELBO can be exactly computed or easily approximated while remaining differentiable w.r.t. (θ, ϕ) . A simple way to approximate $\tilde{Q}(\theta, \phi)$ is by using the reparametrization trick [9] which consists in choosing a parametric distribution $q_{\phi}(\mathbf{z}_T|\mathbf{x}_T)$ such that a sample $\mathbf{z}_T^{(i)} \sim q(\mathbf{z}_T|\mathbf{x}_T)$ can be written as a differentiable function of ϕ .

It remains to choose a variational distribution $q_{\phi}(\mathbf{z}_T|\mathbf{x}_T)$. One popular strategy is to use distributions from a mean-field variational distribution which factorizes as $q_{\phi}(\mathbf{z}_T|\mathbf{x}_T) = q(z_0|\mathbf{x}_T) \prod_{t=1}^t q_{\phi}(z_t|z_{0:t-1}, \mathbf{x}_T)$.

2.2. Semi-supervised Variational Inference for TMC

The TMC is a direct generalization of PMC and HMC to the case where the

In this article, we present the TMC as a generative model which will be used

The distribution $p_{\theta}(\mathbf{x}_T, \mathbf{y}_T, \mathbf{z}_T)$ reads

$$p_{\theta}(z_0, y_0, x_0) \prod_{t=1}^T p_{\theta}(z_t, y_t, x_t | z_{t-1}, y_{t-1}, x_{t-1}). \quad (3)$$

Since only a subset of labels is observed \mathbf{y}_{T^c} , the set of unobserved labels \mathbf{y}_{T^u} is treated as latent variables and variational inference involves finding a lower bound on the

marginal likelihood of the observed data \mathbf{x}_T and \mathbf{y}_{T^c} . The variational lower bound is given by:

$$\log(p_{\theta}(\mathbf{x}_T, \mathbf{y}_{T^c})) \geq - \int \sum_{\mathbf{y}_{T^u}} q_{\phi}(\mathbf{z}_T, \mathbf{y}_{T^u} | \mathbf{x}_T, \mathbf{y}_{T^c}) \times \log \left(\frac{q_{\phi}(\mathbf{z}_T, \mathbf{y}_{T^u} | \mathbf{x}_T)}{p_{\theta}(\mathbf{z}_T, \mathbf{y}_T, \mathbf{x}_T)} \right) d\mathbf{z}_T = Q(\theta, \phi), \quad (4)$$

where ϕ denotes the parameters of the variational distribution $q_{\phi}(\mathbf{z}_T, \mathbf{y}_{T^u} | \mathbf{x}_T, \mathbf{y}_{T^c})$.

Since our model has both discrete and continuous latent variables, the approximation of the ELBO in Eq. (4) becomes more complex. To that end, we can use the Gumbel-Softmax (G-S) trick [10, 11] and the reparametrization trick [9] to approximate $Q(\theta, \phi)$ simultaneously. For the continuous latent variables \mathbf{z}_T , the reparametrization trick introduced in section 2.1 is still valid. On the other hand, for the discrete latent variables \mathbf{y}_{T^u} , the G-S trick enables to obtain a differentiable approximation to the discrete categorical distribution.

It remains to choose a factorization of the variational distribution $q_{\phi}(\mathbf{z}_T, \mathbf{y}_{T^u} | \mathbf{x}_T, \mathbf{y}_{T^c})$, which is a crucial step in variational inference. Different models can be obtained by choosing different factorizations of the variational distribution, which will be discussed in the next section 2.3. For example, we can first consider $q_{\phi}(\mathbf{z}_T, \mathbf{y}_{T^u} | \mathbf{x}_T, \mathbf{y}_{T^c}) = q_{\phi}(\mathbf{z}_T | \mathbf{x}_T, \mathbf{y}_T) q_{\phi}(\mathbf{y}_{T^u} | \mathbf{x}_T, \mathbf{y}_{T^c})$ and then consider a mean-field variational distribution.

2.3. Particular cases of the TMC

The choice of the factorization of the transition distribution $p_{\theta}(z_t, y_t, x_t | z_{t-1}, y_{t-1}, x_{t-1})$ has an impact on the performance of the model for a specific task (classification, prediction, detection or generation). The goal of this section is to present particular cases of our proposed TMC model by choosing different factorizations of the transition and variational distribution. For the sake of clarity, let us now denote the triplet $v_t = (x_t, z_t, y_t)$.

2.3.1. VSL

Variational Sequential Labelers model is a particular case of the TMC model where the transition distribution is factorized as follows:

$$p_{\theta}(v_t | v_{t-1}) = p_{\theta}(y_t | z_t) p_{\theta}(z_t | x_{t-1}, y_{t-1}) p_{\theta}(x_t | z_t). \quad (5)$$

In the case of SVRNN, the chosen variational distribution $q_{\phi}(\mathbf{z}_T, \mathbf{y}_{T^u} | \mathbf{x}_T, \mathbf{y}_{T^c}) = q_{\phi}(\mathbf{z}_T | \mathbf{x}_T, \mathbf{y}_{T^c}) q_{\phi}(\mathbf{y}_{T^u} | \mathbf{x}_T, \mathbf{z}_T, \mathbf{y}_{T^c})$

is given by

$$q_\phi(\mathbf{z}_T|\mathbf{x}_T, \mathbf{y}_{T^c}) = \prod_{t=0}^T q_\phi(z_t|\mathbf{x}_T)$$

$$q_\phi(\mathbf{y}_{T^u}|\mathbf{x}_T, \mathbf{z}_T, \mathbf{y}_{T^c}) = \prod_{t \in \mathcal{U}} q_\phi(y_t|z_t)$$

In particular, VLS considers $q_\phi(y_t|z_t) = p_\theta(y_t|z_t)$.

2.3.2. SVRNN

A Semi-supervised Variational Recurrent Neural Network can be seen as an adapted version of the TMC model where the latent variable z_t is set as (z'_t, h_t) . The variable z'_t is a stochastic latent variable and h_t is deterministically given by $h_t = f_\theta(x_t, y_t, z'_t)$, where f_θ is a deterministic non-linear transition function. In this case, the transition distribution is factorized as follows:

$$p_\theta(v_t|v_{t-1}) = p_\theta(y_t|v_{t-1})p_\theta(z_t|y_t, v_{t-1})p_\theta(x_t|y_t, z_t, v_{t-1}). \quad (6)$$

On the other hand, the chosen variational distribution $q_\phi(\mathbf{z}_T, \mathbf{y}_{T^u}|\mathbf{x}_T, \mathbf{y}_{T^c}) = q_\phi(\mathbf{z}_T|\mathbf{x}_T, \mathbf{y}_T)q_\phi(\mathbf{y}_{T^u}|\mathbf{x}_T, \mathbf{y}_{T^c})$ factorizes as follows:

$$q_\phi(\mathbf{z}_T|\mathbf{x}_T, \mathbf{y}_T) = q_\phi(z_0|\mathbf{x}_t, \mathbf{y}_t) \prod_{t=1}^T q_\phi(z_t|\mathbf{z}_{t-1}, \mathbf{x}_t, \mathbf{y}_t)$$

$$q_\phi(\mathbf{y}_{T^u}|\mathbf{x}_T, \mathbf{y}_{T^c}) = \prod_{t \in \mathcal{U}} q_\phi(y_t|\mathbf{y}_{t-1}, \mathbf{x}_t),$$

2.3.3. mTMC

Finally, we present the minimal TMC which is a particular case of the TMC model presented in [12] where the transition distribution is factorized as follows:

$$p_\theta(v_t|v_{t-1}) = p_\theta(y_t|y_{t-1})p_\theta(z_t|z_{t-1})p_\theta(x_t|t_t, z_t). \quad (7)$$

The variational distribution is chosen as in the SVRNN model.

$$q_\phi(\mathbf{z}_T|\mathbf{x}_T, \mathbf{y}_T) = q_\phi(z_0|\mathbf{x}_t, \mathbf{y}_t) \prod_{t=1}^T q_\phi(z_t|\mathbf{z}_{t-1}, \mathbf{x}_t, \mathbf{y}_t)$$

$$q_\phi(\mathbf{y}_{T^u}|\mathbf{x}_T, \mathbf{y}_{T^c}) = \prod_{t \in \mathcal{U}} q_\phi(y_t|\mathbf{y}_{t-1}, \mathbf{x}_t),$$

3. SIMULATIONS

In this section, we present the results of the proposed models on semi-supervised binary image segmentation. Our goal is to recover the segmentation of a binary image ($\Omega = \{\omega_1, \omega_2\}$) from the noisy observations \mathbf{x}_T when a partially segmentation \mathbf{y}_{T^c} is available.

3.1. Deep TMCs

The set of parameters (θ, ϕ) can be described by any differentiable flexible function $\psi(\cdot)$. In particular, we consider the case where the parameters are produced by a (deep) neural network.

Due to the different factorizations of the generating (resp. variational) distributions, we consider a general notation $p_\theta(x_t|\cdot)$, $p_\theta(z_t|\cdot)$ and $p_\theta(y_t|\cdot)$ (resp. $q_\phi(y_t|\cdot)$, $q_\phi(z_t|\cdot)$) in order to avoid presenting a specific dependence between variables. These dependencies are specified for each model and are presented in the previous Section 2.3. The general model is described by:

$$p_\theta(v_t|v_{t-1}) = p_\theta(x_t|\cdot)p_\theta(z_t|\cdot)p_\theta(y_t|\cdot)$$

$$p_\theta(x_t|\cdot) = \mathcal{N}(x_t; \mu_{px,t}, \text{diag}(\sigma_{px,t})) \quad (8)$$

$$p_\theta(z_t|\cdot) = \mathcal{N}(x_t; \mu_{pz,t}, \text{diag}(\sigma_{pz,t})) \quad (9)$$

$$p_\theta(y_t|\cdot) = \mathcal{B}er(y_t; \rho_{py,t}), \quad (10)$$

where $\text{diag}(\cdot)$ denotes the diagonal matrix deduced from the values of $\sigma_{\cdot,t}$; $[\mu_{\cdot,t}, \sigma_{\cdot,t}]$ and $\rho_{\cdot,t}$ denote the parameters of the Gaussian and Bernoulli distributions, respectively. Finally, the variational distribution is given by

$$q_\phi(z_t|\cdot) = \mathcal{N}(z_t; \mu_{qz,t}, \text{diag}(\sigma_{qz,t})) \quad (11)$$

$$q_\phi(y_t|\cdot) = \mathcal{B}er(y_t; \rho_{qy,t}), \quad (12)$$

The parameters $\theta = \{\mu_{pz,t}, \sigma_{pz,t}, \mu_{px,t}, \sigma_{px,t}, \rho_{py,t}\}$ and $\phi = \{\mu_{qz,t}, \sigma_{qz,t}, \rho_{qy,t}\}$ are derived from neural networks $(\psi_{px}, \psi_{pz}, \psi_{py})$ and (ψ_{qz}, ψ_{qy}) , respectively. Note that in the VLS model $\phi = \{\mu_{qz,t}, \sigma_{qz,t}\}$ since the assumption $q_\phi(y_t|z_t) = p_\theta(y_t|z_t)$ is made. For example, we can consider the deep mTMC model where the parameters are given by:

$$[\mu_{px,t}, \sigma_{px,t}] = \psi_{px}(y_t, z_t)$$

$$[\mu_{qz,t}, \sigma_{qz,t}] = \psi_{qz}(\mathbf{z}_{t-1}, \mathbf{x}_t, \mathbf{y}_t),$$

$$[\mu_{pz,t}, \sigma_{pz,t}] = \psi_{pz}(z_{t-1}),$$

$$\rho_{py,t} = \psi_{py}(y_{t-1})$$

$$\rho_{qy,t} = \psi_{qy}(\mathbf{y}_{t-1}, \mathbf{x}_t).$$

3.2. Experiments settings

We consider the cattle-type and the camel-type images of the Binary Shape Database [13]. The images are transformed into a 1-D signal \mathbf{x}_T with a Hilbert-Peano filling curve [14]. They are next blurred with non-linear noises to highlight the ability, of the models presented in Section 2.3, to learn such a signal corruption. In fact, the cattle-type image is blurred with a general stationary noise and the camel-type image is blurred with a stationary multiplicative noise (more details about generation are given in [12]). On the other hand, the pixels $y_t \in \mathbf{y}_{T^c}$ are randomly chosen. In particular, we consider that 60% of pixels are labeled, the rest of pixels are considered as unobserved.

Each model was trained with stochastic gradient descent on the negative associated ELBO using the Adam optimizer [15]. For each model, ψ . have two hidden layers using rectified linear units, with appropriate outputs (linear, softplus and sigmoid). Additionally, we match the total number of parameters of all models to be equal or close between them, so the number of hidden units, for each hidden layer, is different for each model. The SVRNN (resp. mTMC and VLS) model has 22 (resp. 25 and 41) hidden units.

3.3. Results

The performance of the models is evaluated in terms of the error rate (ER) of the reconstruction of the unobserved pixels.

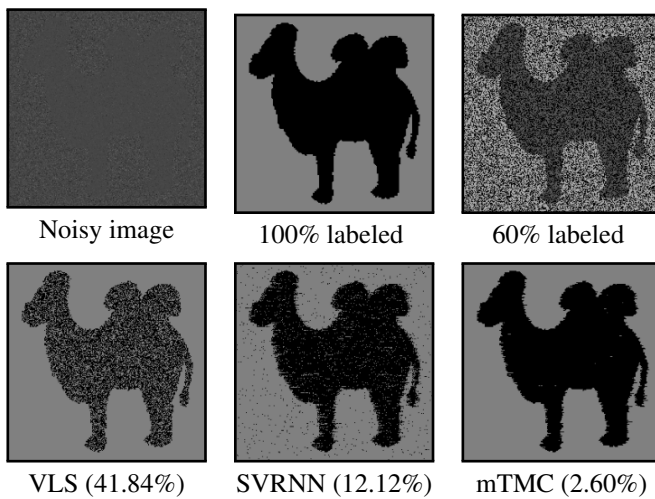

Fig. 1. Semi-supervised image segmentation with TMC models.

3.4. Discussion

4. CONCLUSION

In this paper, we have included some approaches of generative models for semi-supervised learning into a common framework. We have proposed a parameter estimation algorithm for TMCs based on the variational inference framework and adapted to the semi-supervised learning setting. Our experiments have shown that a better performance can be attained with the mTMC

?? and SVRNN ??
than with the VLS
